by define of user

# O.O Programming VS. Generic Programming

---

- In **generic programming** types become known during compilation.
- In O.O programming types become known during **run time**.
- **Generic programming** is a style of computer programming.
- In **generic programming**, we write codes with *to-be-specified-later* types which will be **instantiated** (as required) when we will provide them specific types as extra information through parameters.
- **Templates** are the basis of **generic programming** in C++.
- The Standard Template Library (STL) is a good example of **generic programming**.

# Templates

*{ In function  
In class*

- **Templates** are the foundation of **generic programming** in C++.
- A generic class or a generic function transform into a specific class or function during compilation. We have to provide the information needed to do the transformation.
- A **template** is the structure for creating specific classes or functions.
- All the types which we use in **templates** must be known when we write the program.
- The compiler will generate specific instances of **templates** when we instantiate the **templates** by providing **template** arguments.
- The Standard Library is made up of templates.

# Templates - Example

```
1  #include <iostream>
2
3  template <typename T>
4  T sum( T a, T b)
5  {
6      return (a + b);
7  }
8
9  int main()
10 {
11     int res = sum<int>(3, 4);
12     double res_double = sum<double>(1.0, 3.0);
13     std::string res_string = sum<std::string>("one", "two");
14     int res2 = sum(8, 5); //the compiler find out the T is int
15
16     std::cout << res << std::endl;
17     std::cout << res_double << std::endl;
18     std::cout << res_string << std::endl;
19     std::cout << res2 << std::endl;
20
21     return 0;
22 }
```

*can be anything*

```
7
4
onetwo
13
```

# Templates - instantiation

---

Compiler will generate *type-specific version* of the **templates** for us. Producing type-specific versions of **templates** are referred to as **instantiation** of templates.

**Example-** A specific version of **sum** (from previous slide) with **T** replaced by **int**

```
int sum(int a, int b)
{
    return(a + b);
}
```

# Function Templates

- **Function templates** help us to avoid repeating the body of the functions for every possible types. Therefore, by using **function templates** we can produce different type-specific versions of the same function.

keyword

```
template <typename T>  
{  
    T sum( T a, T b )  
    {  
        return (a + b);  
    }  
}
```

template parameter list

template parameter  
(type parameter)

# Function Templates- template parameter list

- **Template parameter list** is a comma-separated list of one or more **template parameters**.
- **Template parameters** are similar to functions parameters. We must provide template arguments either implicitly or explicitly for the template parameters.

`double res_double = sum<double>(1.0, 3.0);`

*can be define use of type.*

*template argument*

// in the above statement, `double` will bind to the `T` template parameter

`int res2 = sum(8, 5);` // **template argument** is `int` and the compiler deduces this type

*sum<int>(8, 5)*

# Function Templates- specialization of function templates

In function templates, we can define a different implementation for a specific data type:

The image displays C++ code for function templates and their specialization, with several handwritten annotations in red and blue ink.

**Code Snippets:**

```
template<typename T>
T sum(T a, T b)
{
    return a + b;
}

template<>
double sum(double a, double b) // specialization for double
{
    std::cout << "adding two double numbers" << std::endl;
    return a + b;
}

int main()
{
    int res = sum<int>(3, 4);
    double res_double = sum<double>(6.0, 4.0);
    std::cout << res << " " << res_double;
}
```

**Handwritten Annotations:**

- ①** (in blue) points to the `template<typename T>` line.
- ②** (in blue) points to the `template<>` line.
- calling** (in blue) is written vertically next to the `main()` function.
- calling function.** (in red) is written next to the `int res = sum<int>(3, 4);` line.
- without above template, this causes error** (in blue) is written diagonally across the middle.
- specialization for double** (in blue) is written next to the `double sum(double a, double b)` line.
- calling here** (in red) is written next to the `double res_double = sum<double>(6.0, 4.0);` line.
- we double float** (in red) is written next to the `T` in the first template line.
- A red arrow points from the `double` in the specialization line to the `double` in the `main()` function.

**Output:**

```
adding two double numbers
7 10
```

# Templates Parameters – more details

## 1. Template Type Parameters:

```
1  #include <iostream>
2
3  template <typename T, typename U>
4  T sum( T a, U b)
5  {
6      return (a + b);
7  }
8
9  int main()
10 {
11     int res = sum<int, double>(3, 4.5);
12
13     std::cout << res << std::endl;
14
15     return 0;
16 }
```

# Templates Parameters – more details

## 2- `nontype` Template Parameters (nontype parameters):

Nontype parameters are *constant values* rather than types.

```
1  #include <iostream>
2  template <typename T, unsigned value_paramt>
3  T sum( T * ar)
4  {
5      // value_paramt = 5; Error
6      int rs = 0;
7      for (size_t i = 0; i < value_paramt; i++)
8      {
9          rs += ar[i];
10     }
11     return rs;
12 }
13 int main()
14 {
15     int arr[4] = {1,2,3,4};
16     int res = sum<int,4>(arr);
17     std::cout << res;
18 }
```

keyword (type parameter)

nontype parameter

or any other data type

# Class Templates

---

- **Class templates** are formulas to generate type-specific classes.
- **Class templates** are similar to **function templates**. however, the **template parameters** of **class templates** **cannot** be deduced, and so we must provide template arguments as additional information (in contrast to **templates parameters** of function templates which compiler **can** deduce).

# Class Templates - Example

```
1  #include <iostream>
2
3  template <typename T>
4  class Box {
5  public:
6      T box_stuff{}; //attribute box_stuff
7
8      Box(T stuff) { box_stuff = stuff; } // constructor
9
10 };
11
12 int main()
13 {
14     Box<int> myBox{ 76 };
15     std::cout << myBox.box_stuff;
16 }
```

template argument

argument for construction.

# Class Templates – specialization of class templates

In class templates, we can define a different implementation for a specific data type:

```
1  #include <iostream>
2
3  template <typename T>
4  class Box {
5  public:
6      T box_stuff{}; //attribute box_stuff
7      Box(T stuff) { box_stuff = stuff; } // constructor
8  };
9
10 template <>
11 class Box<double*> { //specializing Box for double *
12 public:
13     double* box_stuff{};
14     Box(double stuff) { box_stuff = new double(stuff); }
15 };
16
17 int main()
18 {
19     Box<double*> myBox{ 40 };
20     std::cout << *(myBox.box_stuff);
21     Box<int> secondBox{ 60 };
22     std::cout << secondBox.box_stuff;
23 }
```

---

some other C++ subjects

# Conversion Constructor — the compiler uses them for implicit conversion!

- Constructors with one parameter **implicitly converts** the input arguments to the class of the constructor.
- The compiler uses them as conversion functions.

```
1  class Simple {  
2      int part1;  
3      int part2;  
4      public:  
5          Simple(int a) { part1 = a; part2 = a; }  
6          ~Simple() {}  
7  };  
9  
10 int main()  
11 {  
12     Simple s = 6;  
13 }
```

*constructor, int → Simple.*

Name	Value
s	{part1=6 part2=6 }
part1	6
part2	6

*sign a primitive type to object.  
there have hidden constructor*

# explicit keyword – stop conversion using conversion constructor!

explicit keyword prevents the compiler from using the conversion constructor for implicit conversions

```
1  class Simple {  
2      int part1;  
3      int part2;  
4      public:  
5          explicit Simple(int a) { part1 = a; part2 = a; }  
6          ~Simple() {}  
7  };  
8  
9  
10 int main()  
11 {  
12     Simple s = 6; //ERROR  
13     Simple simple = Simple(6);  
14 }
```

*stop to use broken  
constructor to conversion.*

	Code	Description
	C2440	'initializing': cannot convert from 'int' to 'Simple'
	E0415	no suitable constructor exists to convert from "int" to "Simple"

*→ can't convert number to object*

# Friend classes and Friend methods -Example

---

For a class:

- A **friend method** can access the **private** and **protected** members of the class in which it is declared as a friend. The **friend method of a class** is **not** considered as the member function of the class.
- All of the members of a **friend class** can access the private and protected members of the class in which it is declared as a friend.

# Friend classes and Friend methods - example

```
1  #include <iostream>
2
3  class Simple {
4      int part1; } private
5      int part2;
6  public:
7      Simple() :part1(1), part2(1) { };
8      Simple(int a) { part1 = a; part2 = a; }
9      ~Simple() {}
10     friend class VerySimple;
11     friend int myFriendMethod(Simple);
12 };
13
```

can  
access  
to  
Simple class  
variable

## Friend classes and Friend methods - example

```
14  class VerySimple {  
15      Simple se;  
16  public:  
17      VerySimple() {}  
18      void VerySimpleMethod(int a) { se.part1 = a; se.part2 = a; }  
19  };  
20  
21  int myFriendMethod(Simple se)  
22  {  
23      return se.part1;  
24  }  
25  
26  int main()  
27  {  
28      Simple si = 9;  
29      std::cout << myFriendMethod(si) << std::endl;  
30      VerySimple vs;  
31  
32  }
```
